

Delegating Authority to AI Agents

Give an agent a narrow, time-boxed, revocable slice of your authority — provable to anyone, enforced at runtime, fully audited.

The missing trust layer for agentic AI is not “*can this agent reach the tool?*” — it is “**is this agent authorized to do this, on whose behalf, and within what limits?**” We answer that with a government-trust **EU Digital Identity mandate** the agent carries, and a **Mandamus/WAUTH** runtime that enforces it and receipts every action.

TWO WORLDS, BRIDGED — THE MOAT

EU Digital Identity — portable proof
The agent carries a verifiable **power-of-representation mandate** credential. Any EU relying party can verify its delegated authority with standard wallet protocols. Authority becomes *interoperable*.

↔
BIND

Mandamus / WAUTH — enforced authority
Governs the agent *as it acts*: the authorization gate, **human step-up (iProov)** for consequential actions, and **tamper-evident signed receipts**. Authority becomes *accountable*.

The EU credential is the **verifiable face** of a Mandamus mandate. Competitors do one side; together they do both.

GUARANTEES THAT MATTER

- An agent can never exceed its grant**
Monotonic narrowing — a delegate holds only a *subset* of the delegator’s powers. Proven in Lean.
- Post-quantum from day one**
Hybrid-PQ on the most sensitive new authority surface — ahead of the EU itself.
- Human-in-the-loop where it counts**
High-consequence actions require a fresh iProov biometric, bound into the authorization.
- Instant kill-switch**
One tap revokes an agent; it stops being verifiable immediately (status-list revocation).
- Every action is receipted**
A hash-chained audit trail — accountability record and reputation signal in one.

WHERE THE HUMAN STAYS IN CONTROL

EU Wallet — “My Agents”
You grant, scope, revoke and approve the big moves.

Mandamus — govern
Policy, receipts and agent reputation at runtime.

The agent — just runs
A Mac app, an iPhone app, or in the cloud. Its key is hardware-protected — Secure Enclave on device; HSM/TEE with remote attestation in the cloud. The mandate is bound to *that* key, so it can’t be lent out.

Issue (**VCIssuer**) → Hold & grant (**EU Wallet**) → Present (**Agent**) → Verify (**VCVerifier**) → Enforce & receipt (**Mandamus**)

HONEST POSITIONING

The EU has the **legal hook** for mandates (Reg. 2024/1183, Annex VI) but **no standard yet for delegating to a machine agent**. That is the gap we fill — as a formally-verified, post-quantum extension, ready to converge when the EU rulebook lands.

STATUS

FIRST SLICE VERIFIED
Design agreed; building **core-first** across five repos. The issuer’s delegation decision kernel — narrowing, PQ, delegate-key binding, revocation — is implemented with **12/12 tests green** and its Lean proof mirror in progress. Next: issuer service → verifier → wallet journey → agent runtime + receipts → end-to-end.
